# Redundancy at OSI Layer 1 and 2

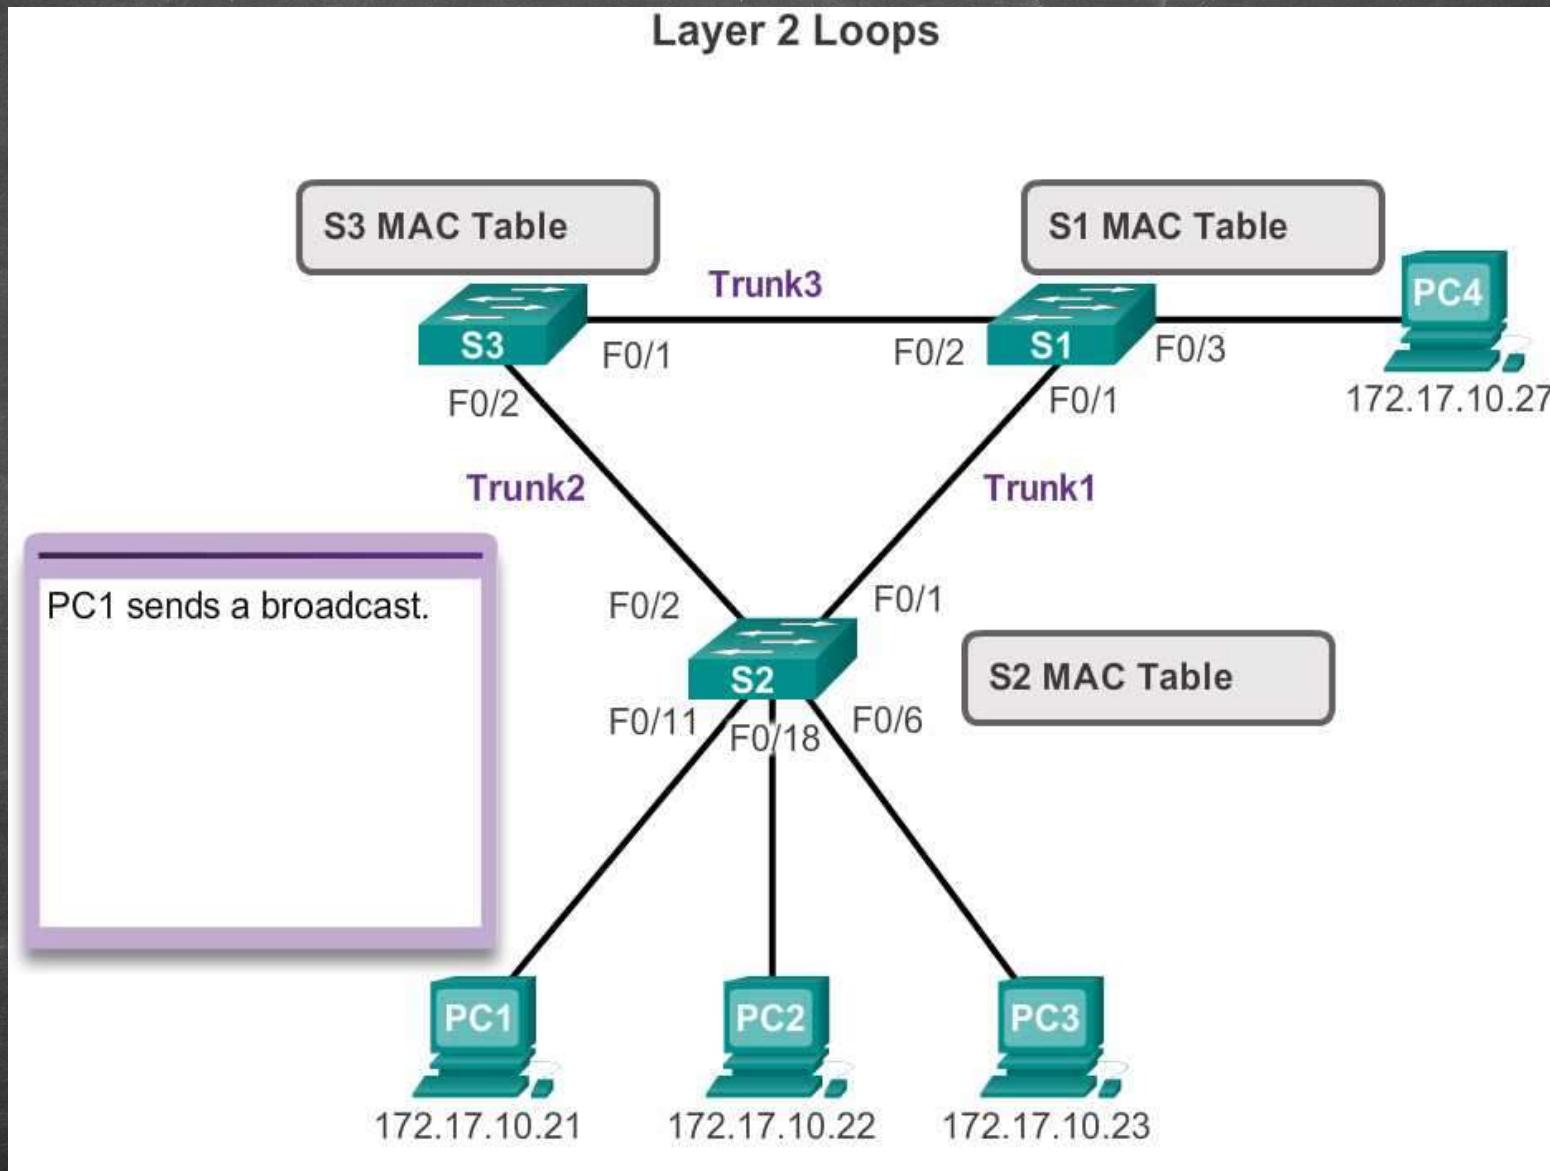

# Issues with Layer 1 Redundancy

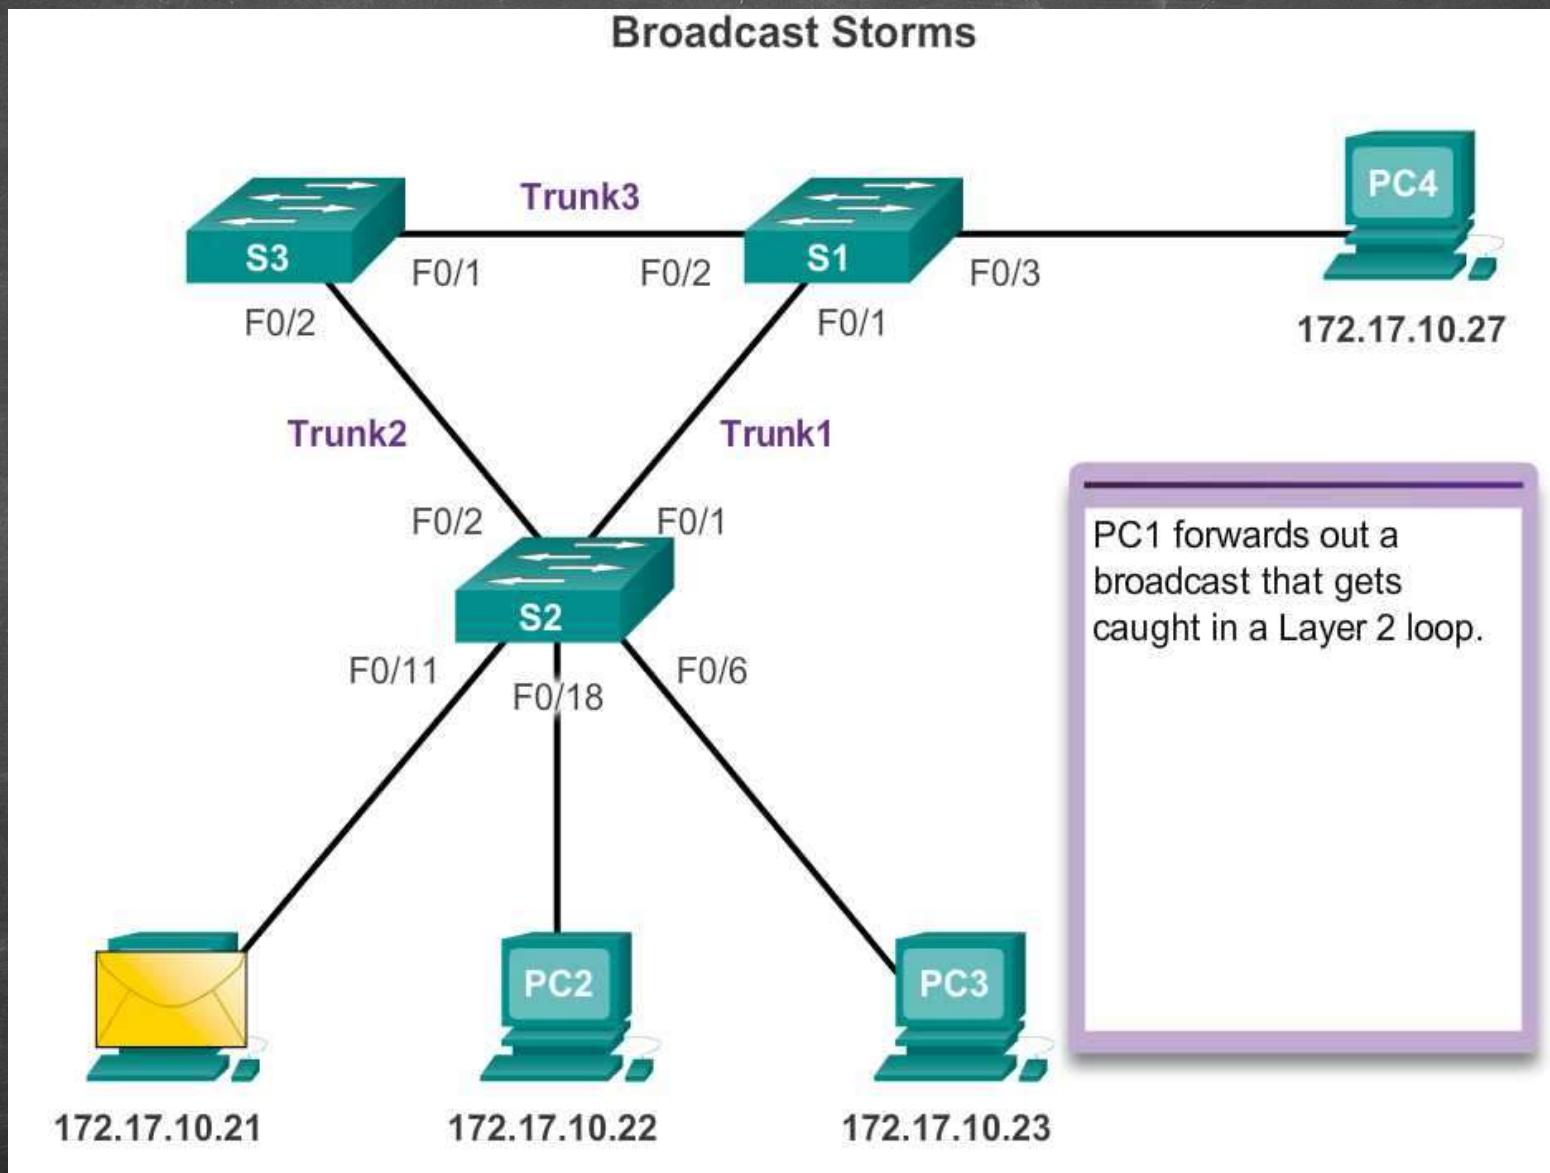

## Considerations When Implementing Redundancy:

- **MAC database instability** - Instability in the content of the MAC address table results from copies of the same frame being received on different ports of the switch. Data forwarding can be impaired when the switch consumes the resources that are coping with instability in the MAC address table.
- **Broadcast storms** - Without some loop-avoidance process, each switch may flood broadcasts endlessly. This situation is commonly called a broadcast storm.
- **Multiple frame transmission** - Multiple copies of unicast frames may be delivered to destination stations. Many protocols expect to receive only a single copy of each transmission. Multiple copies of the same frame can cause unrecoverable errors.

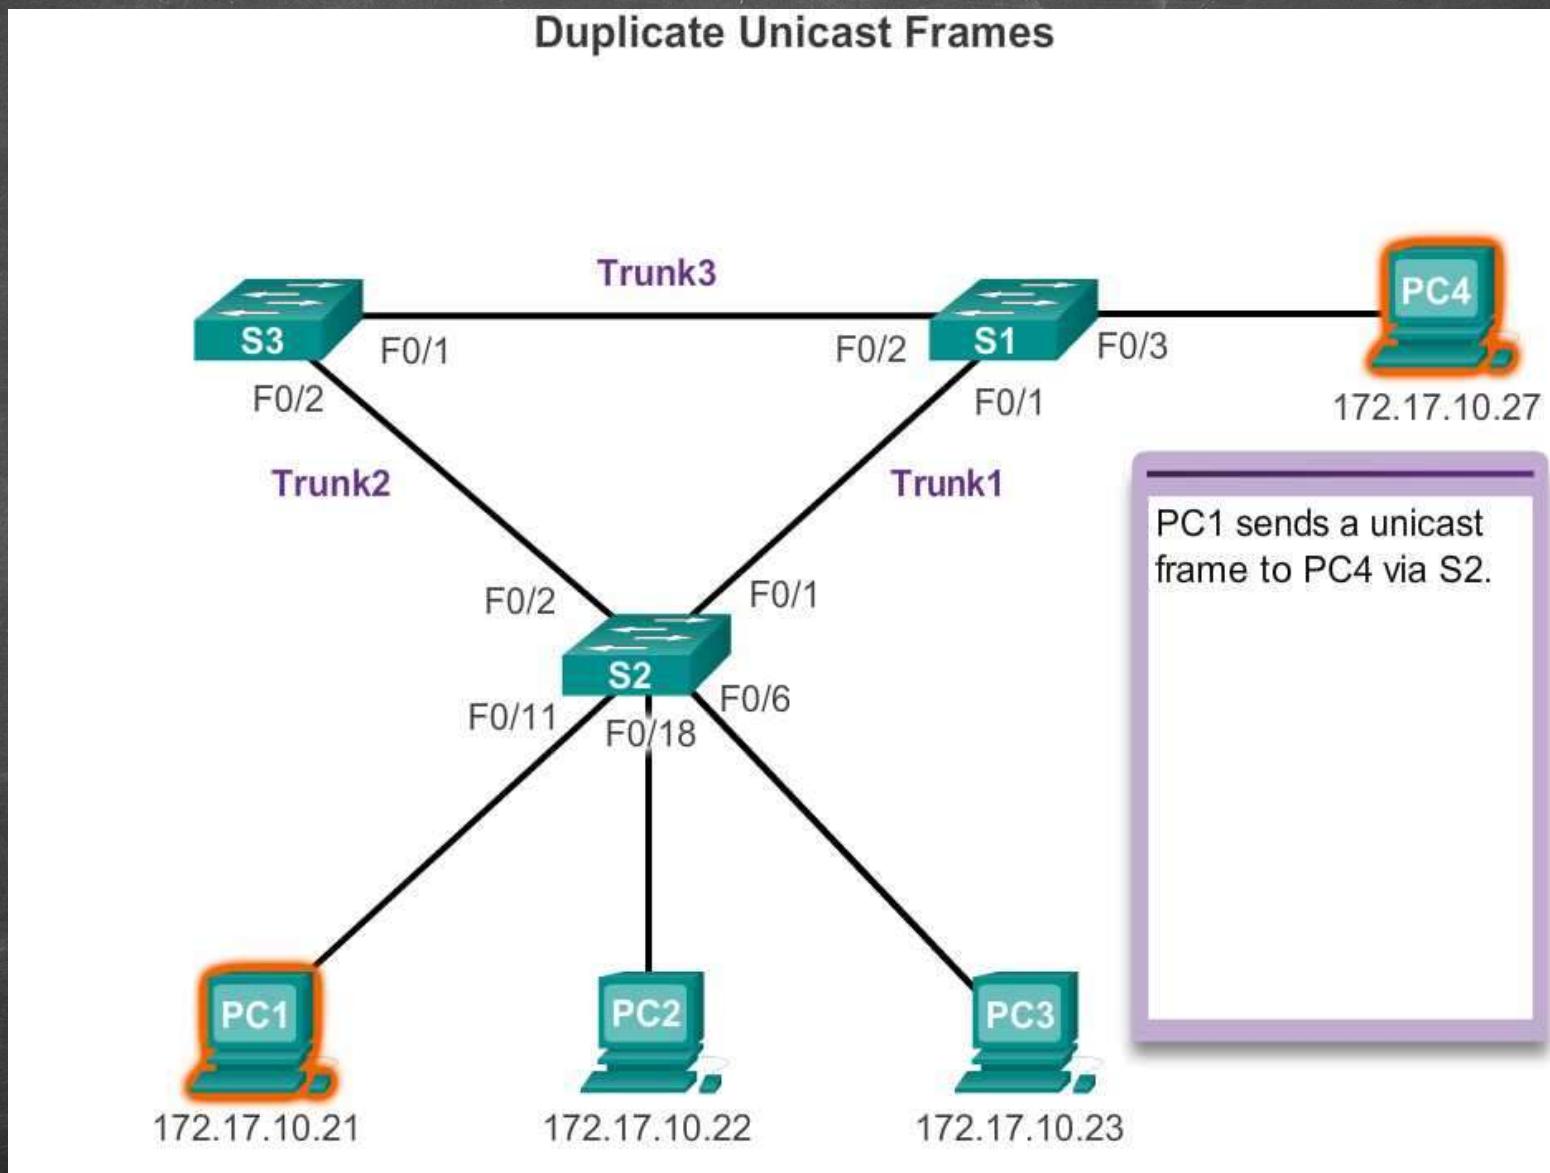

# MAC Database Instability

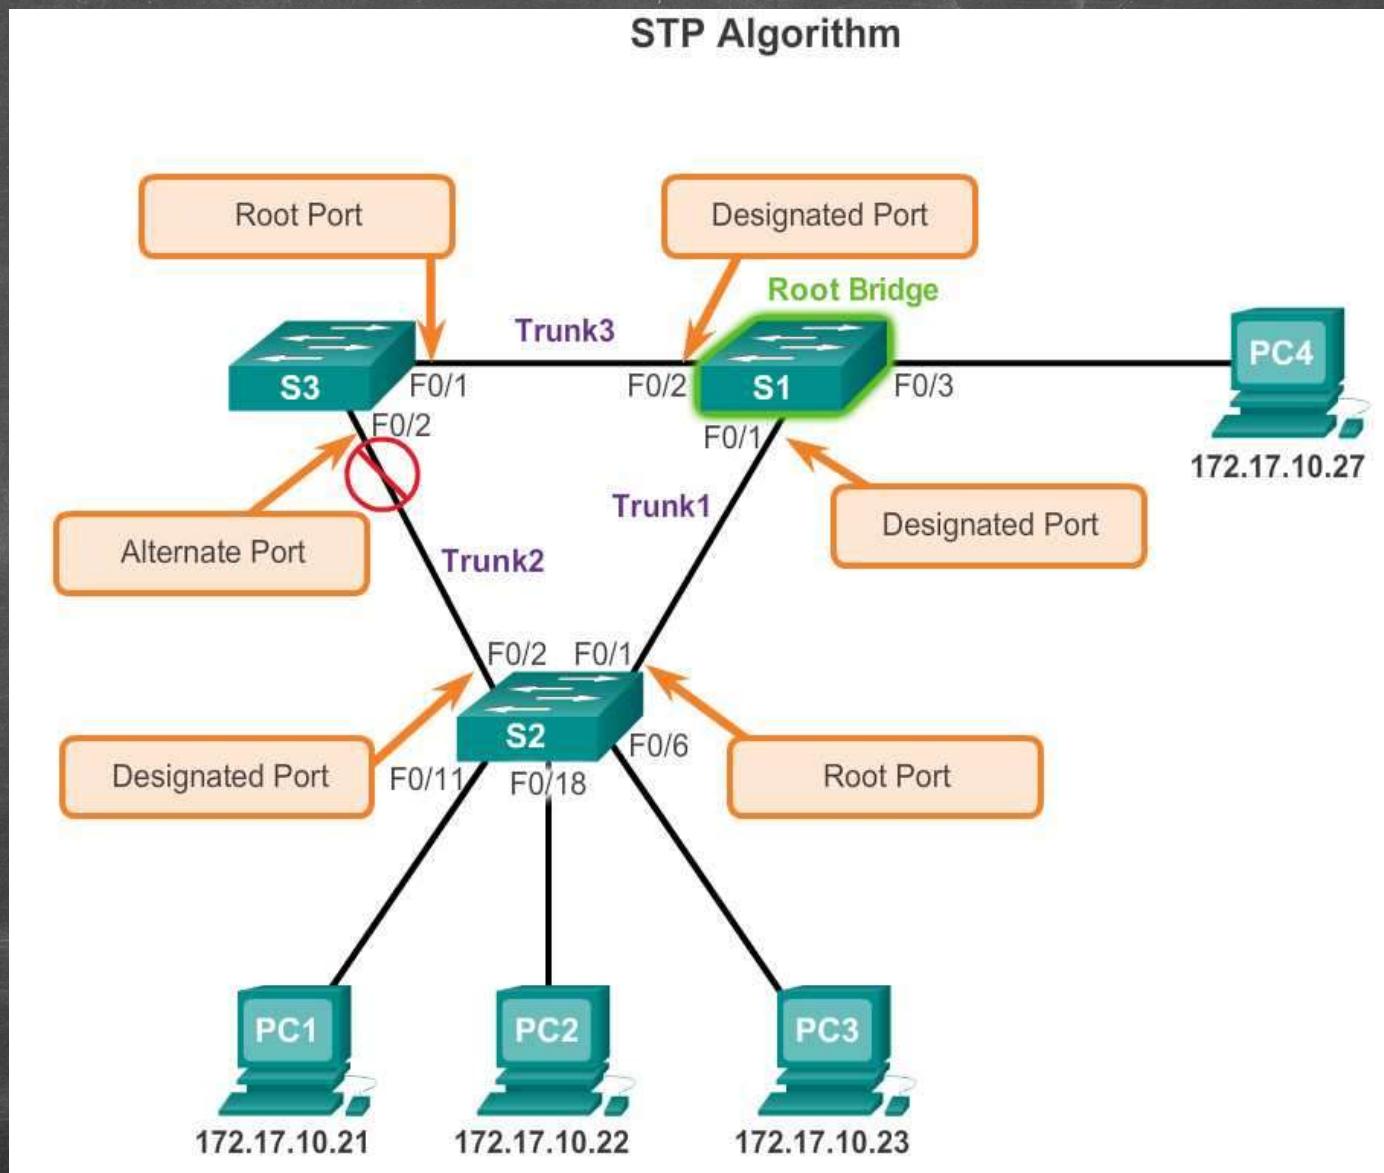

# Broadcast Storm

# Multiple Frame Transmissions

# Spanning Tree Protocol

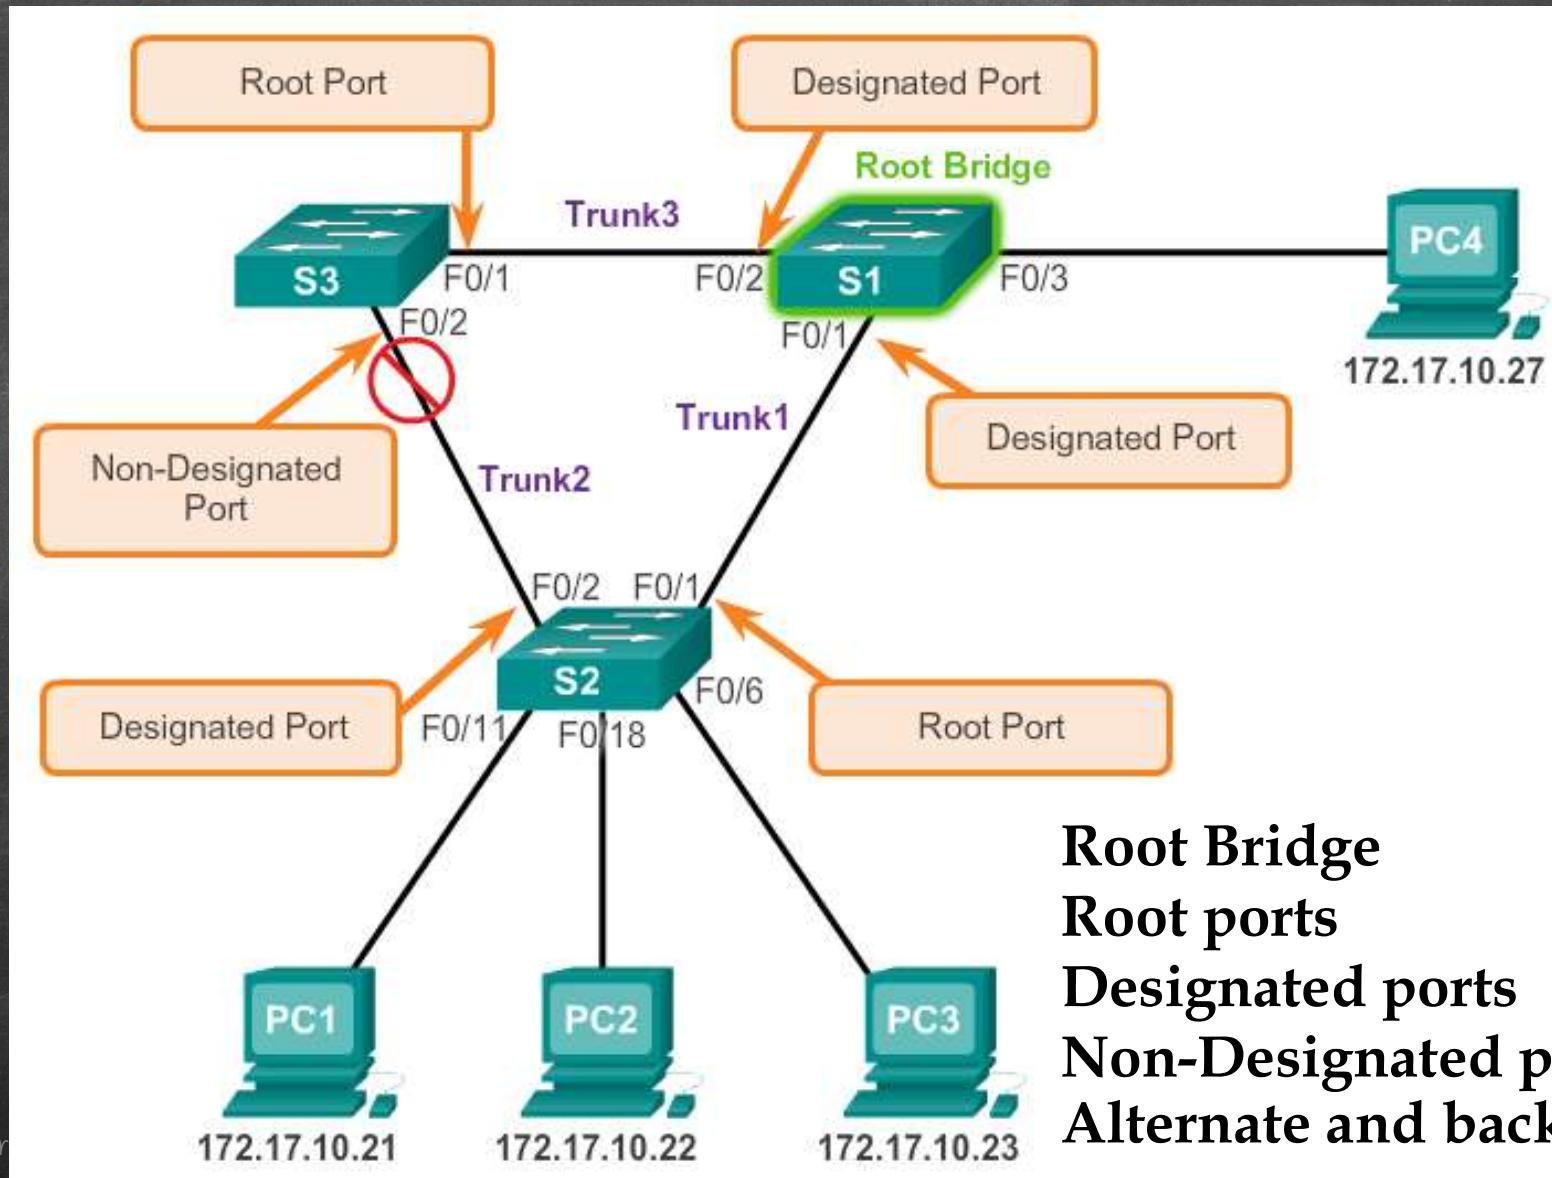

# Spanning Tree Algorithm

- Introduction
  - STP ensures that there is only one logical path between all destinations on the network by intentionally blocking redundant paths that could cause a loop.
  - A port is considered blocked when user data is prevented from entering or leaving that port. This does not include bridge protocol data unit (BPDU) frames that are used by STP to prevent loops.
  - The physical paths still exist to provide redundancy, but these paths are disabled to prevent the loops from occurring.
  - If the path is ever needed to compensate for a network cable or switch failure, STP recalculates the paths and unblocks the necessary ports to allow the redundant path to become active.

# Varieties of Spanning Tree Protocols

- Characteristics of the Spanning Tree Protocols

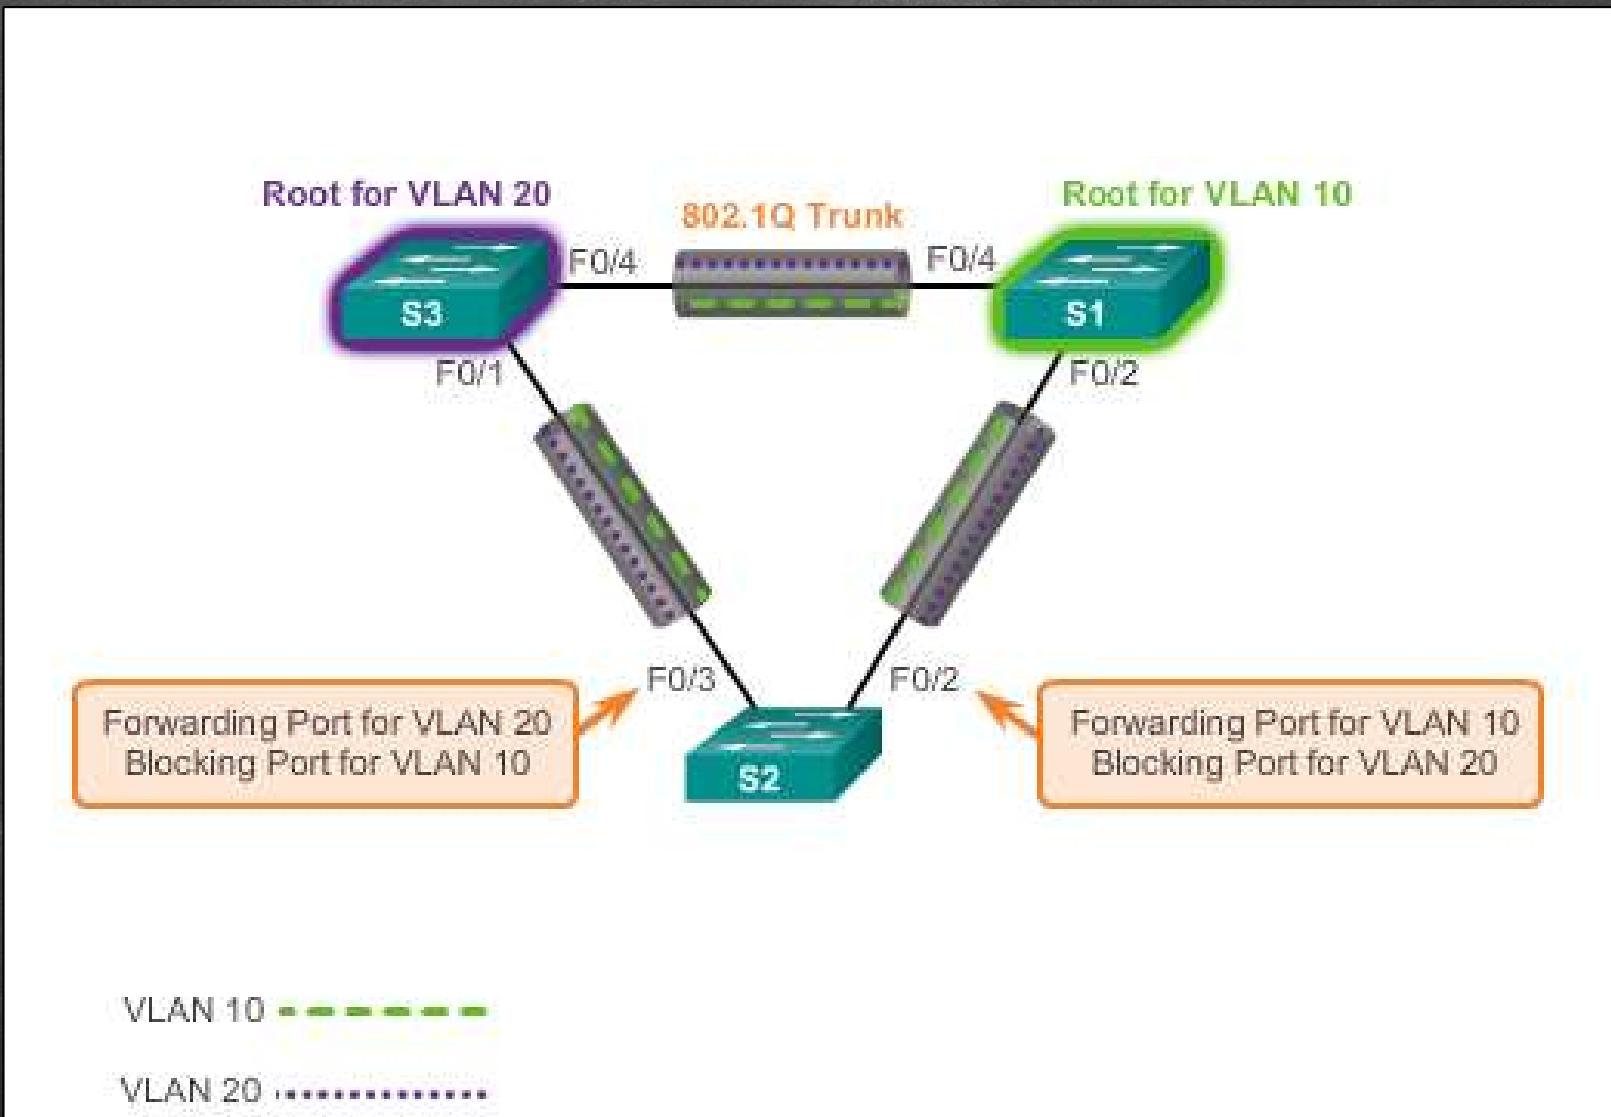

Protocol	Standard	Resources Needed	Convergence	Tree Calculation
STP	802.1D	Low	Slow	All VLANs
PVST+	Cisco	High	Slow	Per VLAN
RSTP	802.1w	Medium	Fast	All VLANs
Rapid PVST+	Cisco	Very high	Fast	Per VLAN
MSTP	802.1s Cisco	Medium or high	Fast	Per Instance

# PVST+

- Overview of PVST+
  - Networks running PVST+ have these characteristics:
    - A network can run an independent IEEE 802.1D STP instance for each VLAN in the network.
    - Optimum load balancing can result.
    - One spanning-tree instance for each VLAN maintained can mean a considerable waste of CPU cycles for all the switches in the network. In addition to the bandwidth that is used for each instance to send its own BPDU.

# PVST+

- Overview of PVST+

# PVST+

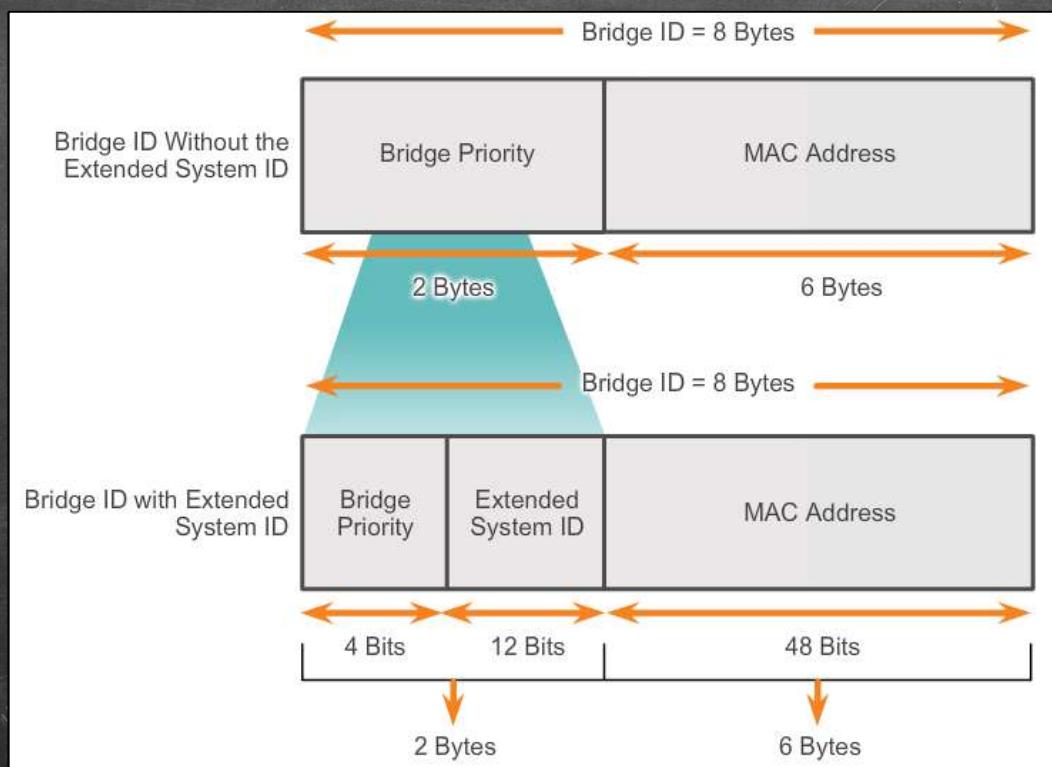

- Port States and PVST+ Operation

Port States

Processes	Blocking	Listening	Learning	Forwarding	Disabled
Processes received BPDUs	YES	YES	YES	YES	NO
Forward data frames received on interface	NO	NO	NO	YES	NO
Forward data frames switched from another interface	NO	NO	NO	YES	NO
Learn MAC addresses	NO	NO	YES	YES	NO

# PVST+

- Extended System ID and PVST+ Operation
  - In a PVST+ environment, the extended switch ID ensures each switch has a unique BID for each VLAN.
  - For example, the VLAN 2 default BID would be 32770; priority 32768, plus the extended system ID of 2.

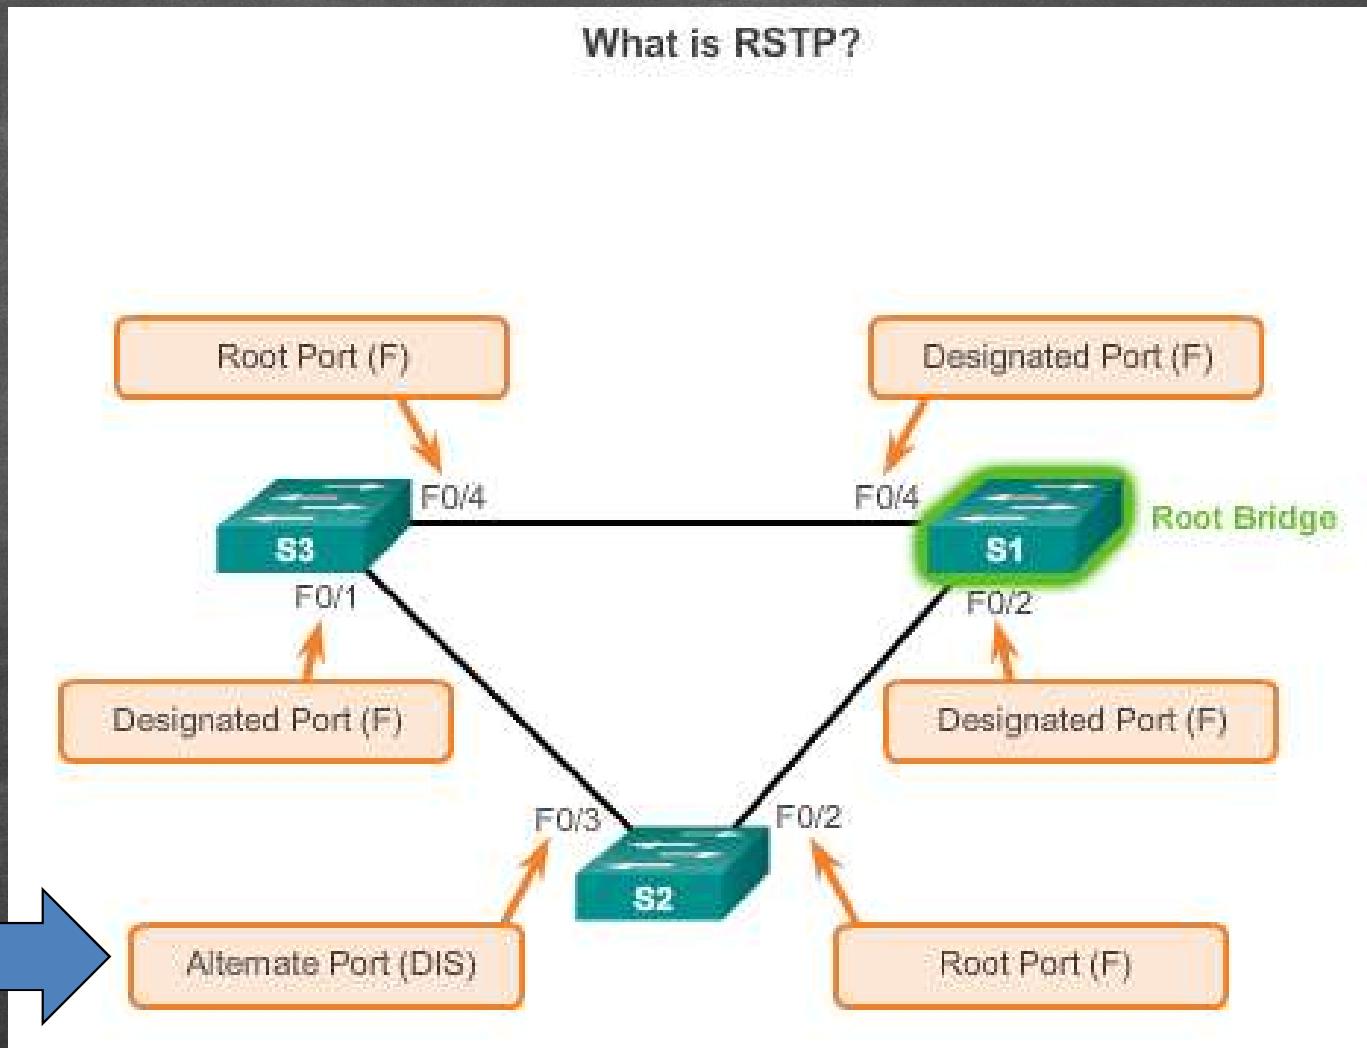

# Rapid PVST+

- Overview of Rapid PVST+
  - RSTP is the preferred protocol for preventing Layer 2 loops in a switched network environment.
  - With Rapid PVST+, an independent instance of RSTP runs for each VLAN.
  - RSTP supports a new port type: an alternate port in discarding state.
  - There are no blocking ports. RSTP defines port states as discarding, learning, or forwarding.
  - RSTP (802.1w) supersedes STP (802.1D) while retaining backward compatibility
  - RSTP keeps the same BPDU format as IEEE 802.1D, except that the version field is set to 2 to indicate RSTP, and the flags field uses all 8 bits.

# Rapid PVST+

- Overview of Rapid PVST+

# Rapid PVST+

- RSTP BPDU

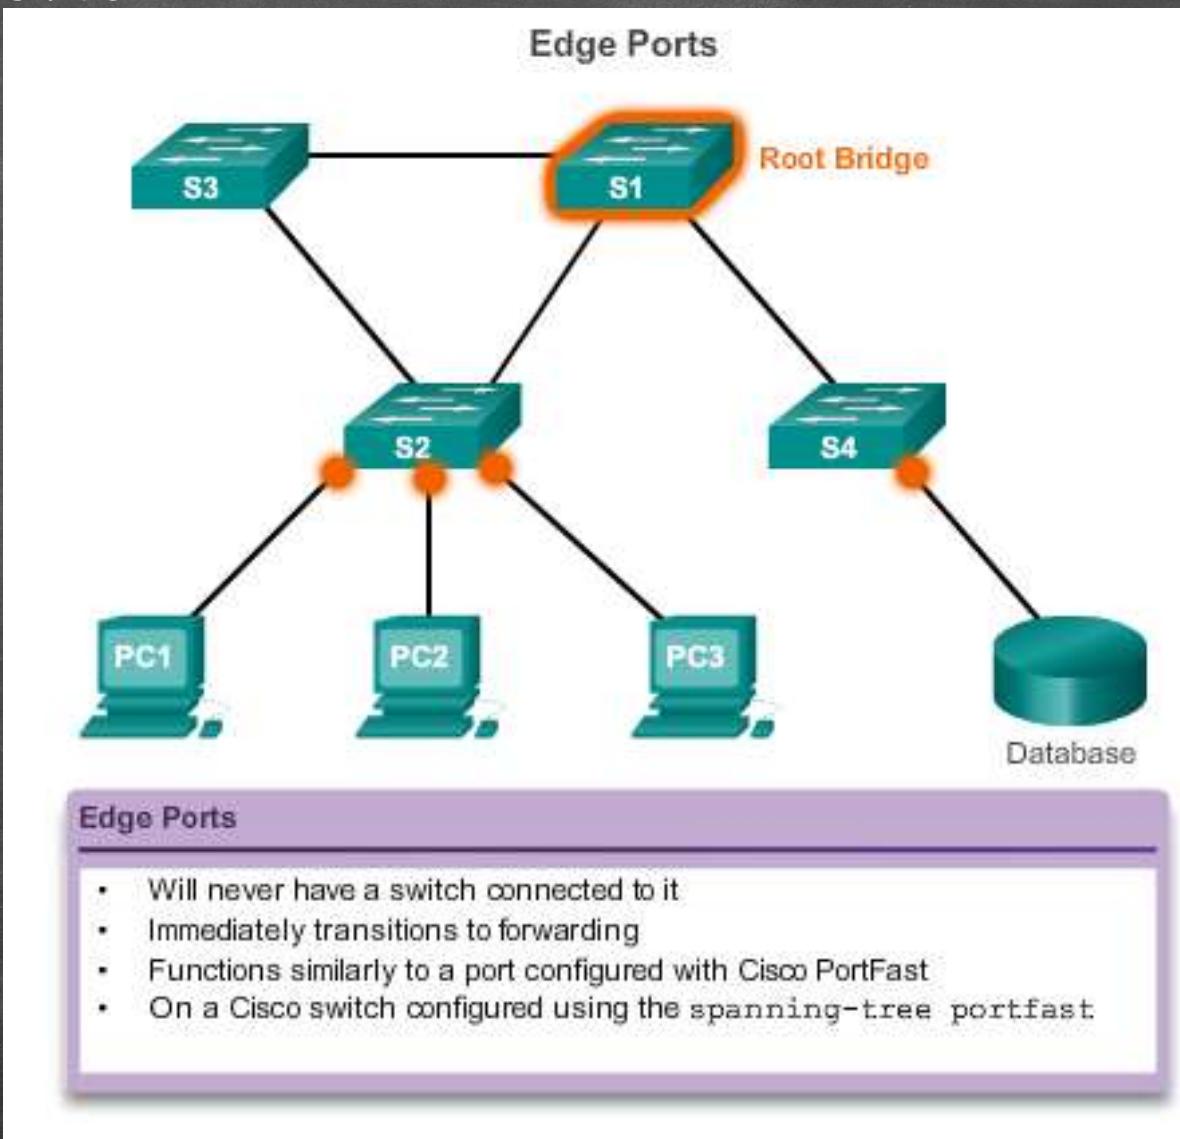

RSTP Version 2 BPDU	
Field	Byte Length
Protocol ID=0x0000	2

# Rapid PVST+

- Edge Ports

# Rapid PVST+

- Link Types

– The link type can determine whether the port can immediately transition to forwarding state. Edge port connections and point-to-point connections are candidates for rapid transition to forwarding state.

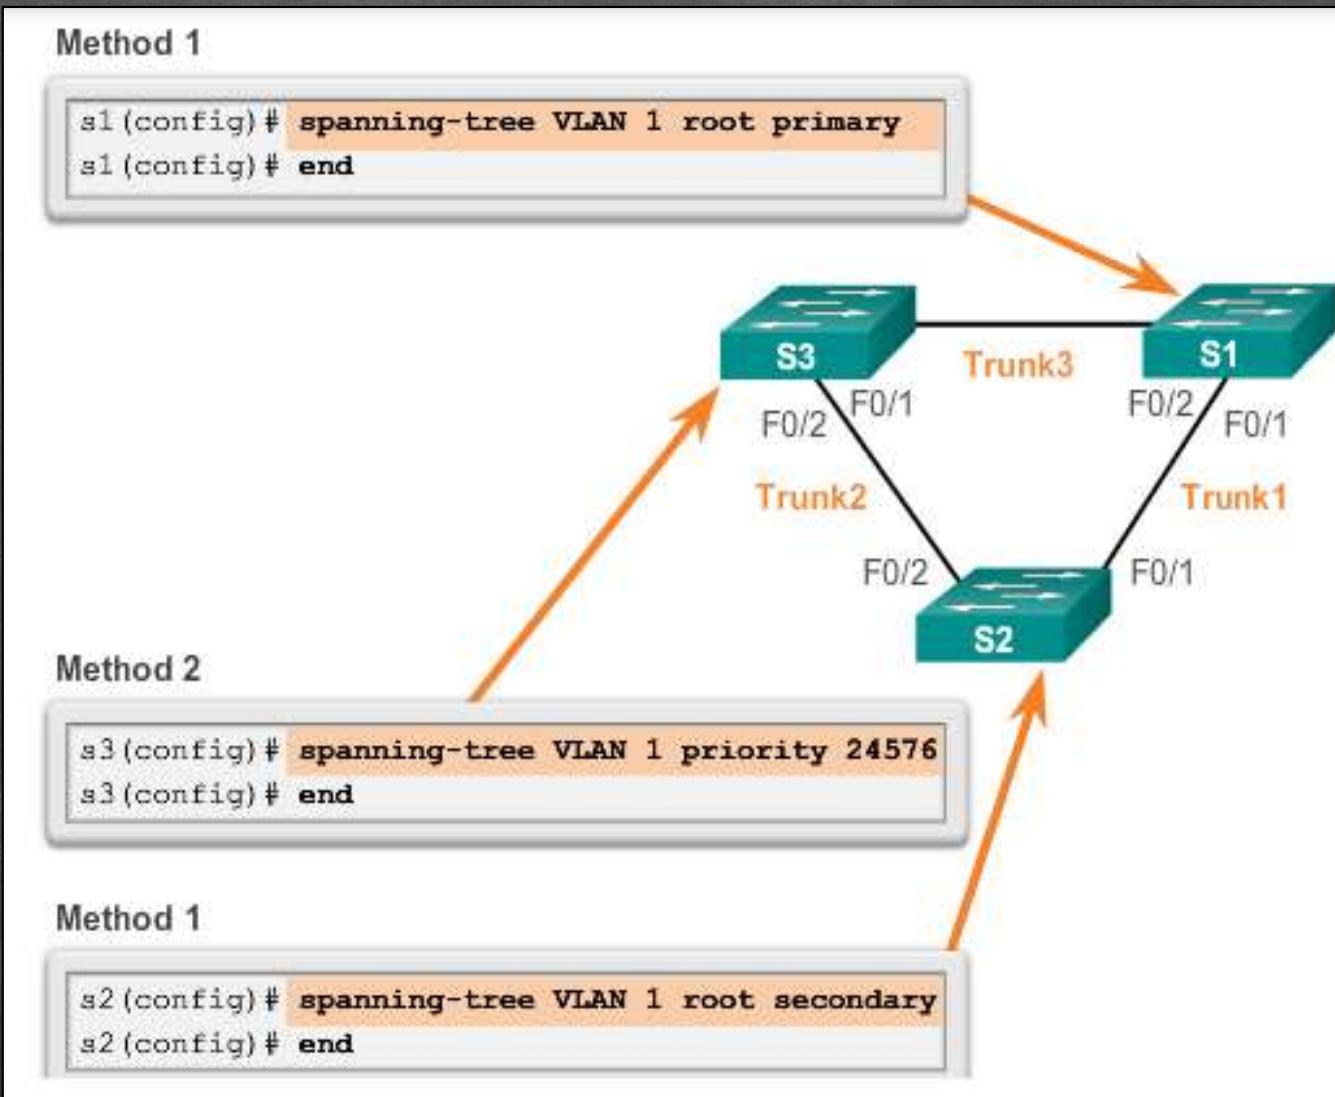

# Spanning Tree Configuration

- Catalyst 2960 Default Configuration

Feature	Default Setting
Enable state	Enabled on VLAN 1
Spanning-tree mode	PVST+ (Rapid PVST+ and MSTP are disabled.)
Switch priority	32768
Spanning-tree port priority (configurable on a per-interface basis)	128
Spanning-tree port cost (configurable on a per-interface basis)	1000 Mb/s: 4 100 Mb/s: 19 10 Mb/s: 100
Spanning-tree VLAN port priority (configurable on a per-VLAN basis)	128
Spanning-tree VLAN port cost (configurable on a per-VLAN basis)	1000 Mb/s: 4 100 Mb/s: 19 10 Mb/s: 100
Spanning-tree timers	Hello time: 2 seconds Forward-delay time: 15 seconds Maximum-aging time: 20 seconds Transmit hold count: 6 BPDUs

# Spanning Tree Configuration

S3#
```

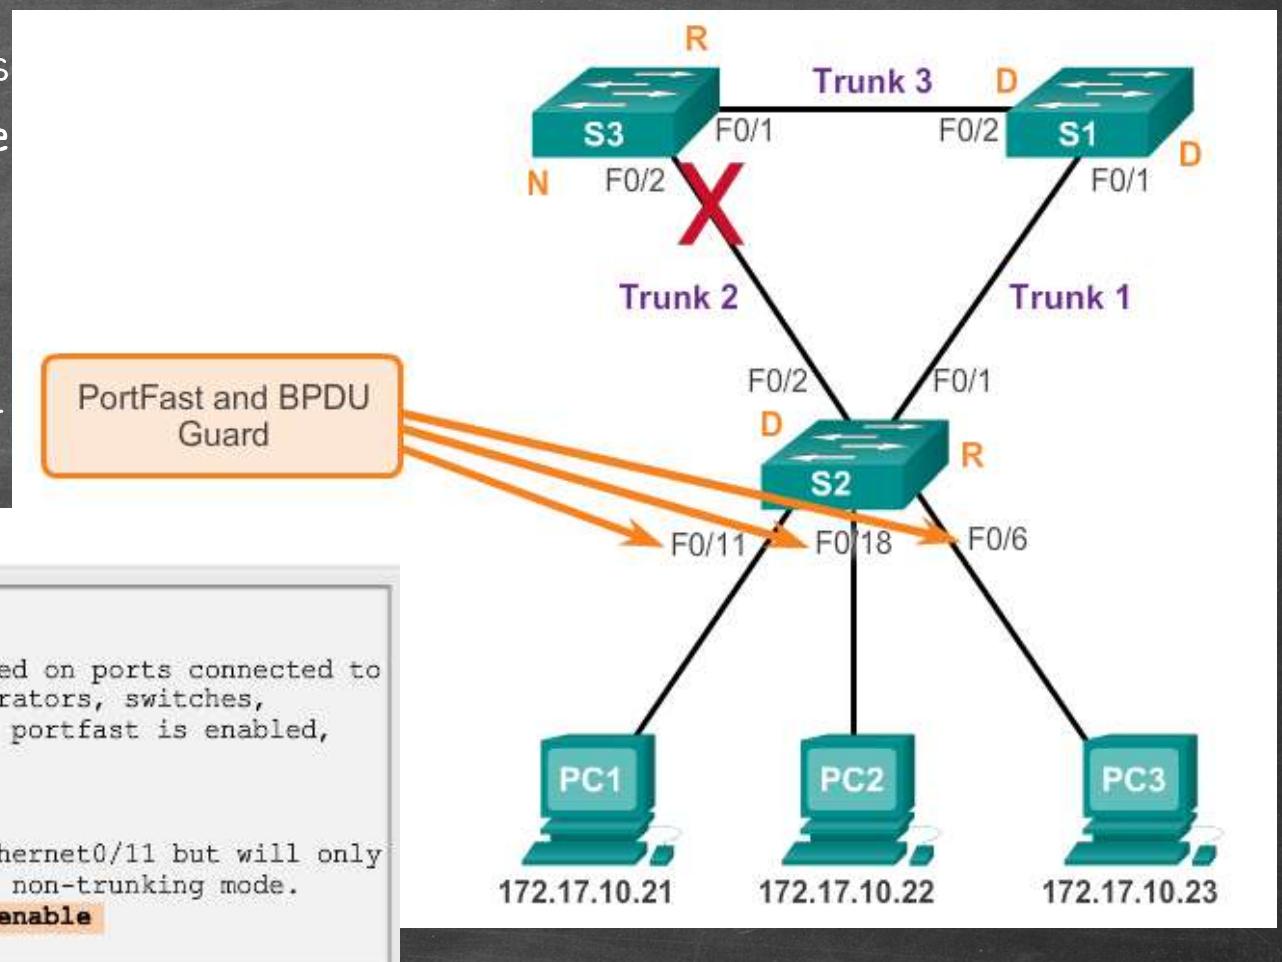

# Spanning Tree Configuration

- PortFast and BPDU Guard

- When a switch port is configured with PortFast that port transitions from blocking to forwarding state immediately.
- BPDU guard puts the port in an error-disabled state on receipt of a BPDU.

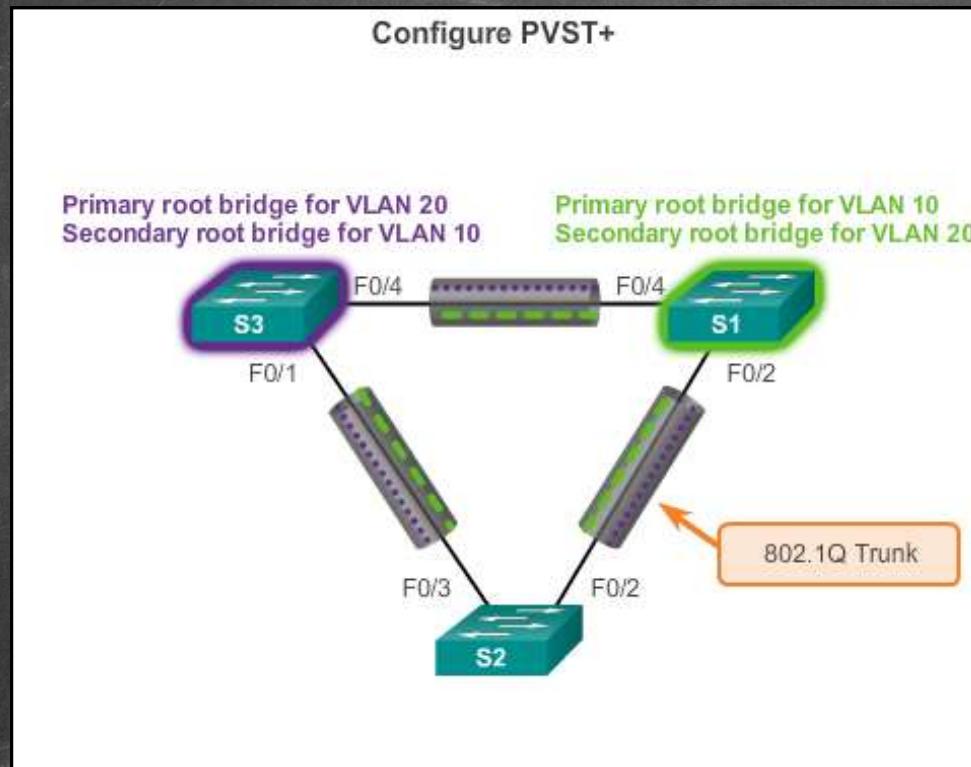

```
S2(config)# interface FastEthernet 0/11
S2(config-if)# spanning-tree portfast
%Warning: portfast should only be enabled on ports connected to
a single host. Connecting hubs, concentrators, switches,
bridges, etc... to this interface when portfast is enabled,
can cause temporary bridging loops.
Use with CAUTION

%Portfast has been configured on FastEthernet0/11 but will only
have effect when the interface is in a non-trunking mode.
S2(config-if)# spanning-tree bpduguard enable
S2(config-if)# end
```

# Spanning Tree Configuration

- PVST+ Load Balancing

**Configure PVST+**

```
S3(config)# spanning-tree vlan 20 root primary
```

This command forces S3 to be the primary root for VLAN 20.

```
S3(config)# spanning-tree vlan 10 root secondary
```

This command forces S3 to be the secondary root for VLAN 10.

```
S1(config)# spanning-tree vlan 10 root primary
```

This command forces S1 to be the primary root for VLAN 10.

```
S1(config)# spanning-tree vlan 20 root secondary
```

This command forces S1 to be the secondary root for VLAN 20.

# Spanning Tree Configuration

- PVST+ Load Balancing
  - Another method to specify the root bridge is to set the spanning tree priority on each switch to the lowest value so that the switch is selected as the primary bridge for its associated VLAN.

## Configure PVST+

```
S3(config)# spanning-tree vlan 20 priority 4096
```

This command sets the priority for S3 to be the lowest possible, making it most likely that S3 will be the primary root for VLAN 20.

```
S1(config)# spanning-tree vlan 10 priority 4096
```

This command sets the priority for S1 to be the lowest possible, making it most likely that S1 will be the primary root for VLAN 10.

# Spanning Tree Configuration

- PVST+ Load Balancing
  - Display and verify spanning tree configuration details

**Configure PVST+**

```
S3# show spanning-tree active

# Spanning Tree Configuration

- Rapid PVST+ Configuration

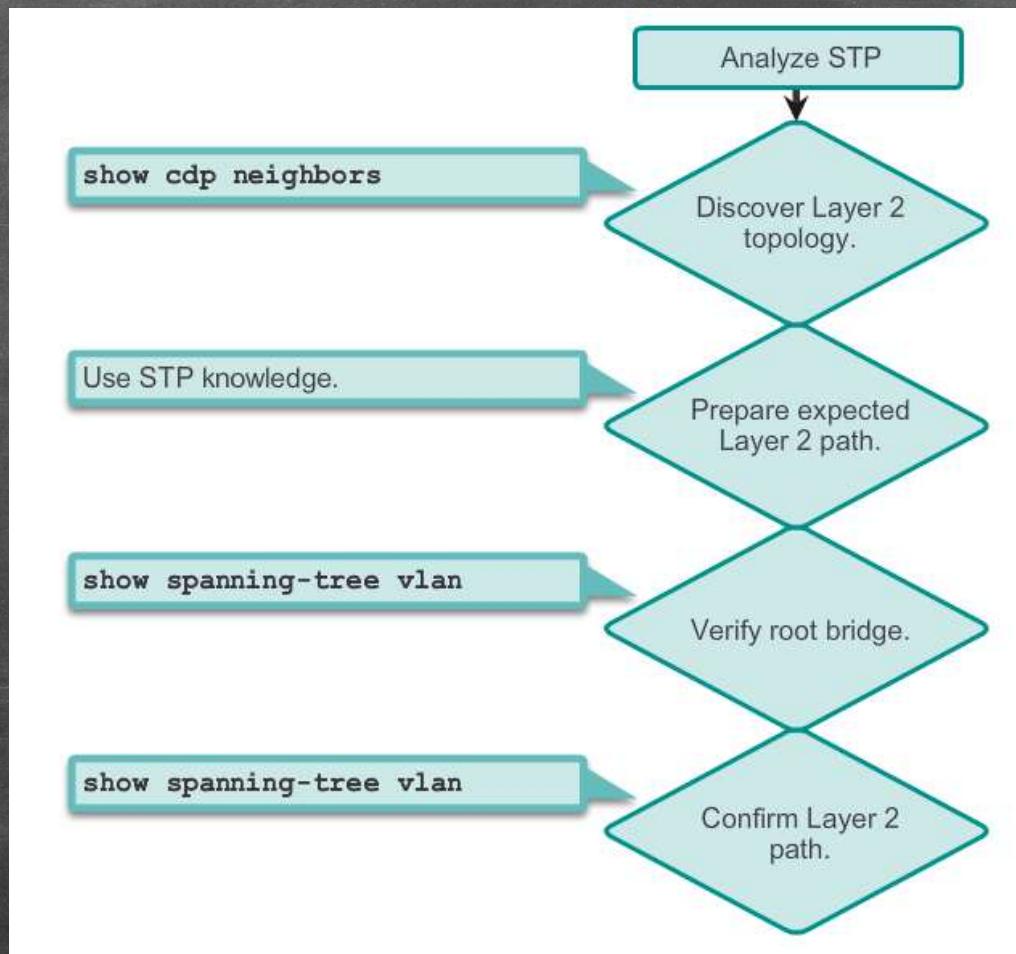

Rapid PVST+ is the Cisco implementation of RSTP. It supports RSTP on a per-VLAN basis.

```
S1# configure terminal
S1(config)# spanning-tree mode rapid-pvst
S1(config)# interface f0/2
S1(config-if)# spanning-tree link-type point-to-point
S1(config-if)# end
S1# clear spanning-tree detected-protocols
```

Cisco IOS Command Syntax	
Enter global configuration mode.	<b>configure terminal</b>
Configure Rapid PVST+ spanning-tree mode.	<b>spanning-tree mode rapid-pvst</b>
Enter interface configuration mode and specify an interface to configure. Valid interfaces include physical ports, VLANs, and port channels.	<b>interface interface-id</b>
Specify that the link type for this port is point-to-point.	<b>spanning-tree link-type point-to-point</b>
Return to privileged EXEC mode.	<b>end</b>
Clear all detected STP.	<b>clear spanning-tree detected-protocols</b>

- STP Configuration Issues
  - Expected Topology versus Actual Topology

# Spanning Tree Configuration

- STP Configuration Issues
  - Overview of Spanning Tree Status

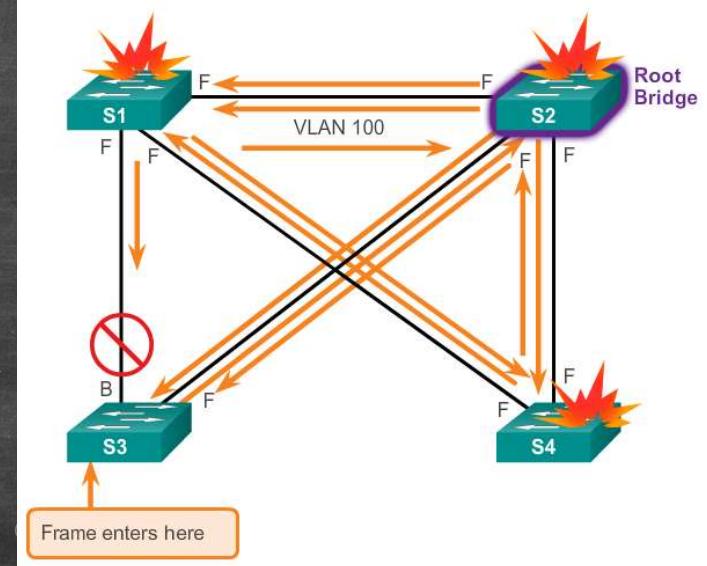

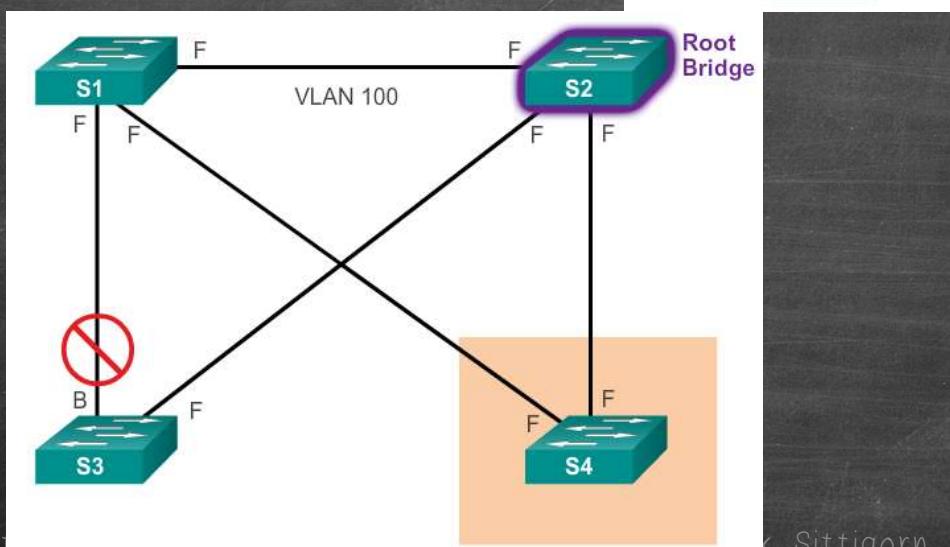

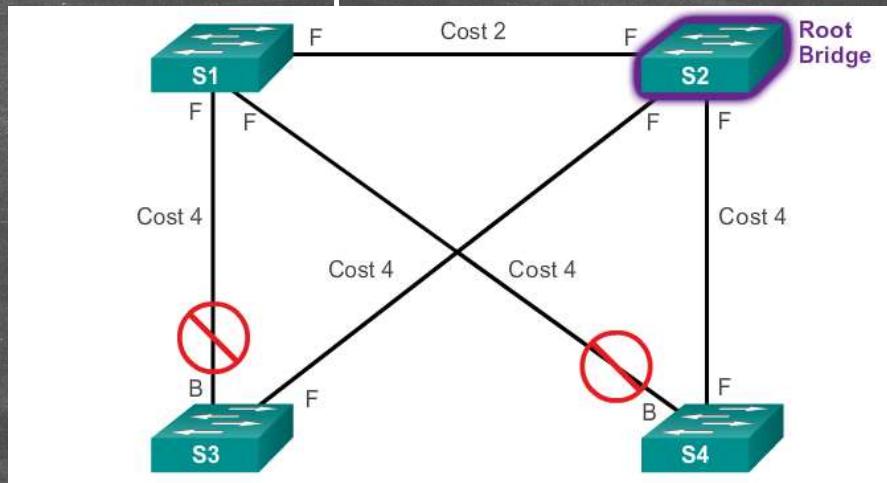

# Spanning Tree Configuration

- STP Configuration Issues

- Spanning-Tree Failure Consequences

- STP erroneously moves one or more ports into the forwarding state.
- Any frame that is flooded by a switch enters the loop.

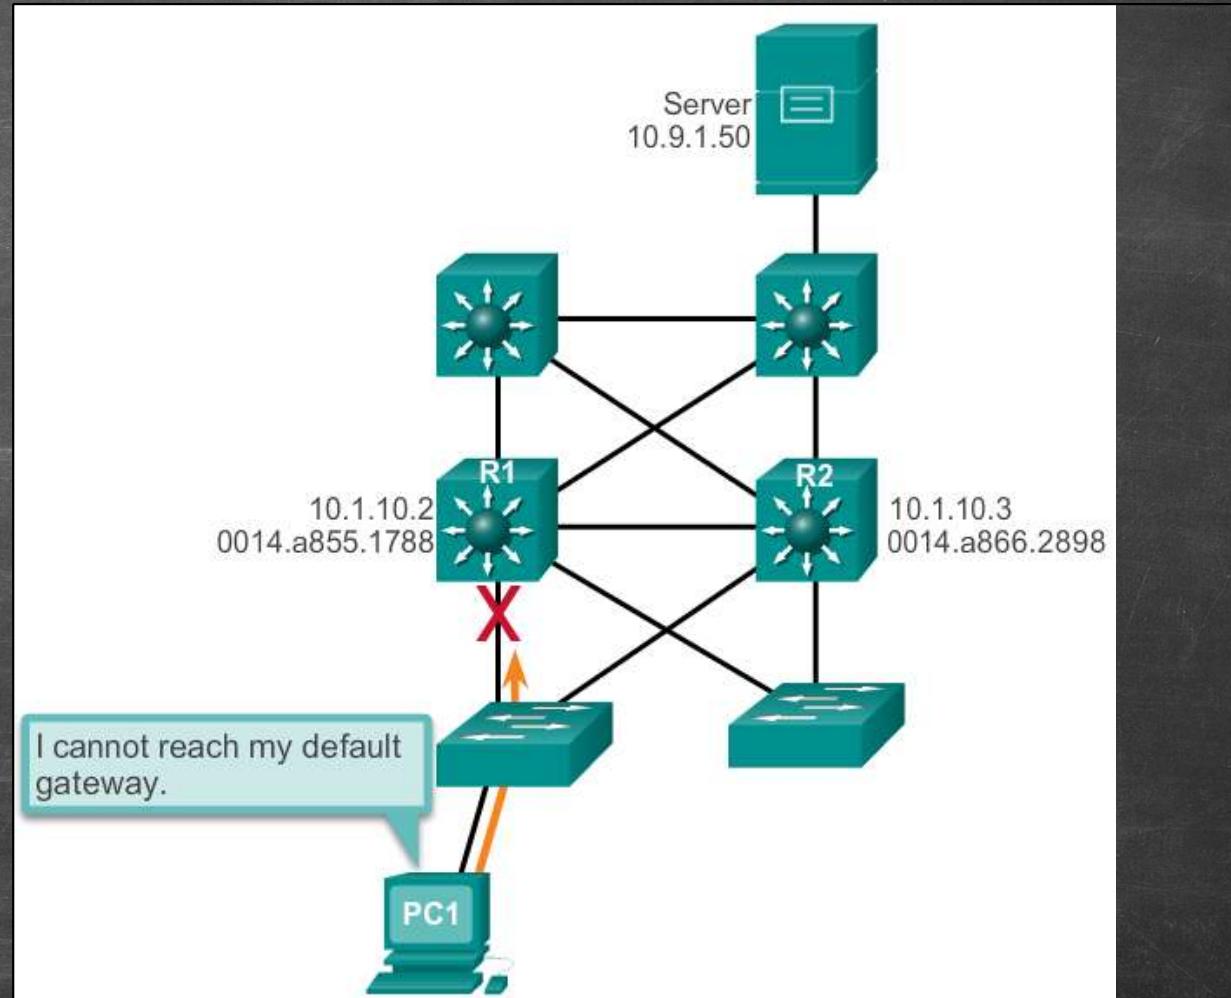

# Spanning Tree Configuration

- STP Configuration Issues
  - Repairing a Spanning Tree Problem
    - One way to correct spanning-tree failure is to manually remove redundant links in the switched network, either physically or through configuration, until all loops are eliminated from the topology.
    - Before restoring the redundant links, determine and correct the cause of the spanning-tree failure.
    - Carefully monitor the network to ensure that the problem is fixed.

# First-Hop Redundancy Protocols

- Default Gateway Limitations

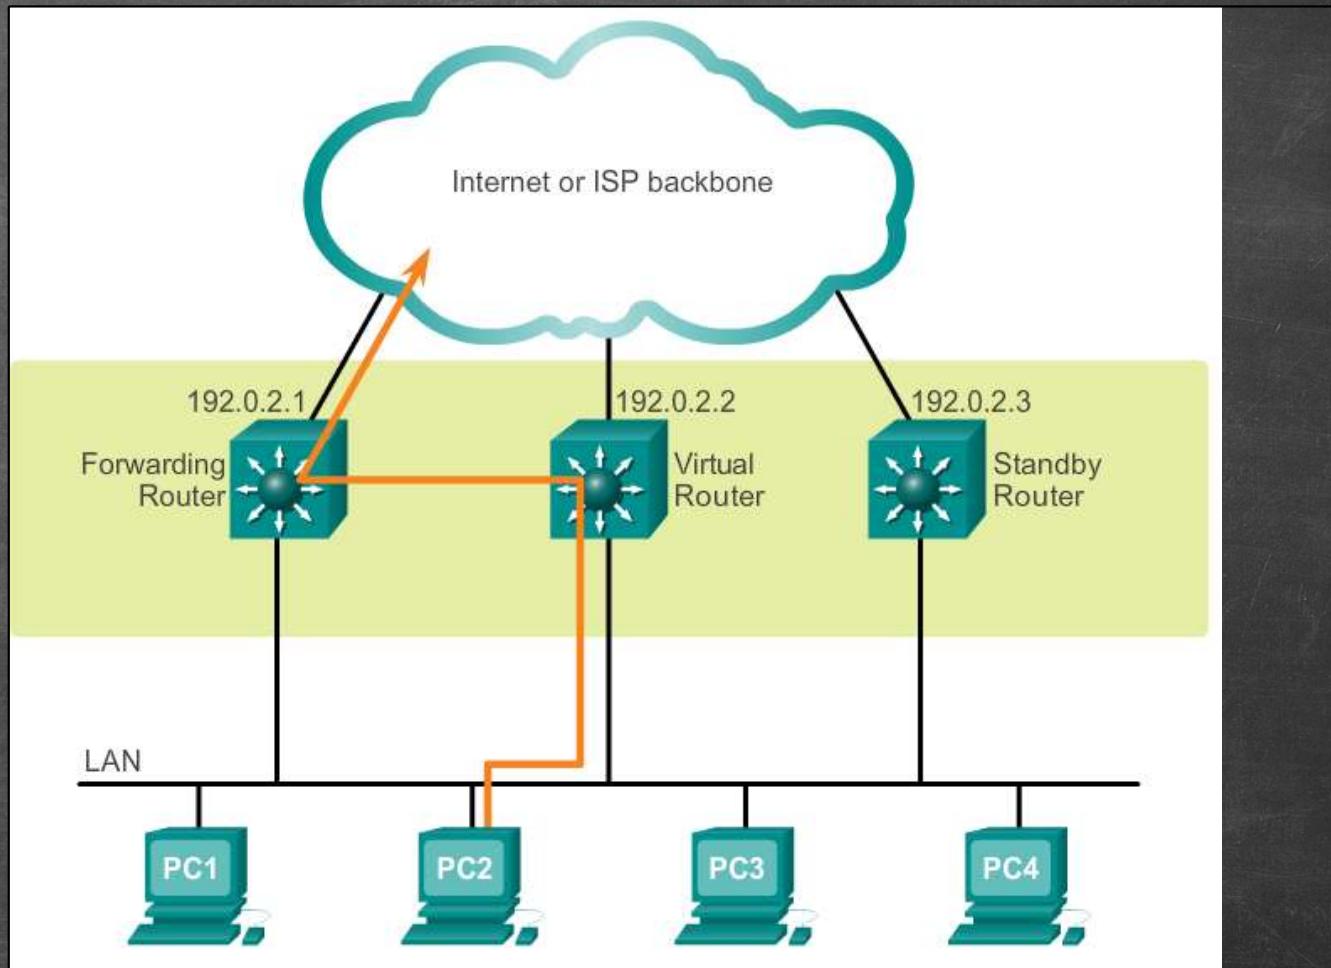

- If the default gateway cannot be reached, the local device is unable to send packets off the local network segment.
- Even if a redundant router exists that could serve as a default gateway for that segment, there is no dynamic method by which these devices can determine the address of a new default gateway.

# First-Hop Redundancy Protocols

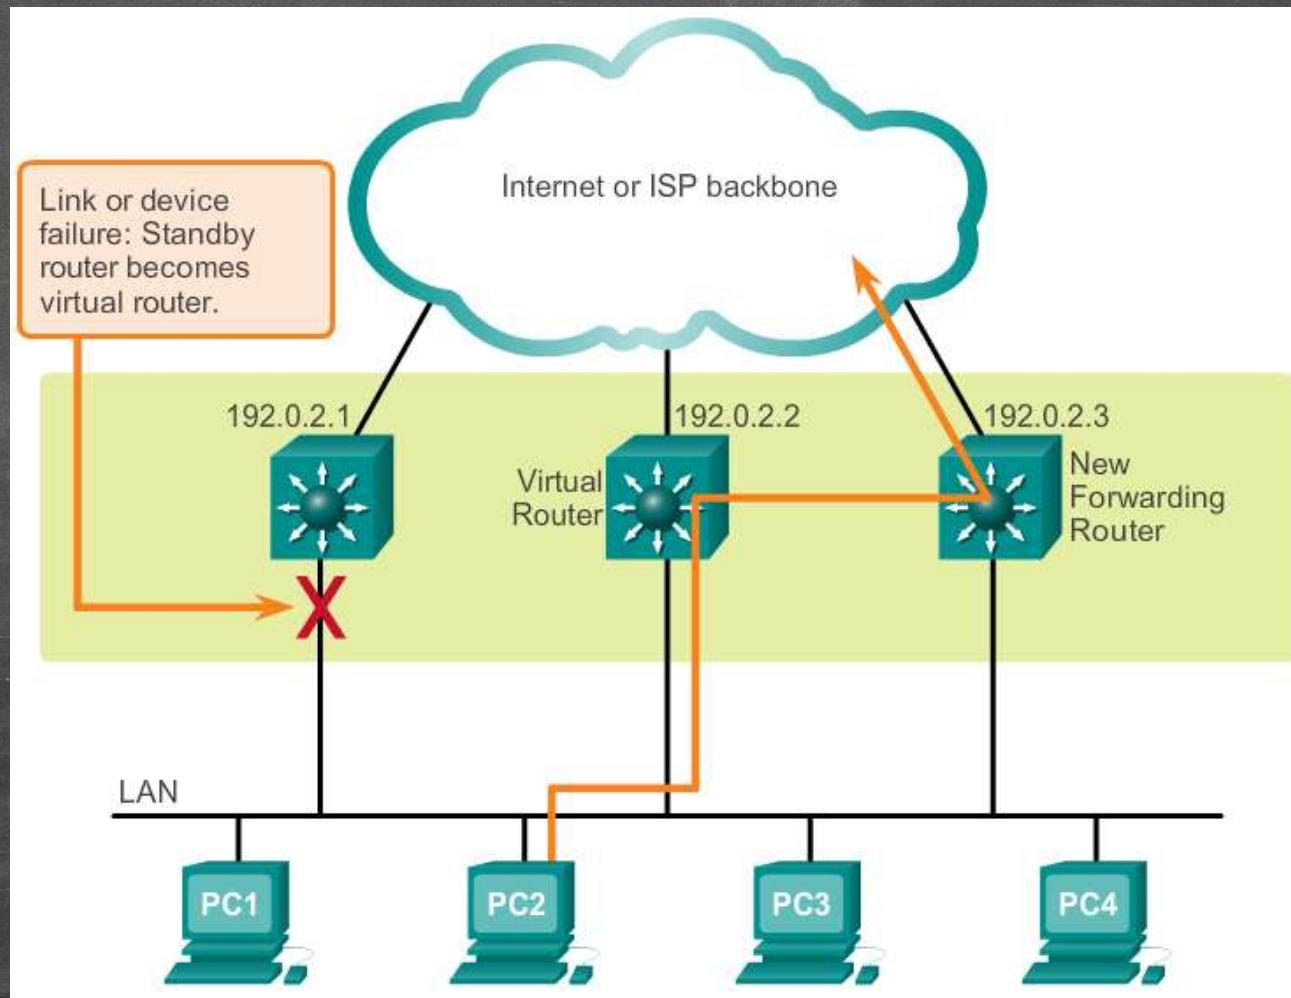

- Router Redundancy

- Multiple routers are configured to work together to present the illusion of a single router to the hosts on the LAN.
- The ability of a network to dynamically recover from the failure of a device acting as a default gateway is known as first-hop redundancy.

# First-Hop Redundancy Protocols
